Certificate Information

The following Ada implementation was tested and determined to pass ACVC 1.11. Testing was completed on October 12, 1994.

Compiler Name and Version: Green Hills Optimizing Ada Compiler,
Version 1.8.7 with PATCH ID 1

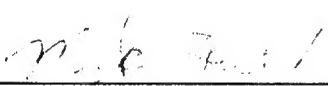

Host Computer System: COMPAQ ProLiant 2000 Model 5/66 under SCO
UNIX, Release 3.2, Version 4.2

Target Computer System: COMPAQ ProLiant 2000 Model 5/66 under SCO
UNIX, Release 3.2, Version 4.2

See section 3.1 for any additional information about the testing environment.

As a result of this validation effort, Validation Certificate 941012S1.11379 is awarded to TISOFT, INC.. This certificate expires 2 years after ANSI/MIL-STD-1815B is approved by ANSI.

This report has been reviewed and is approved.

CHAPTER 1

INTRODUCTION

The Ada implementation described above was tested according to the Ada Validation Procedures [Pro92] against the Ada Standard [Ada83] using the current Ada Compiler Validation Capability (ACVC). This Validation Summary Report (VSR) gives an account of the testing of this Ada implementation. For any technical terms used in this report, the reader is referred to [Pro92]. A detailed description of the ACVC may be found in the current ACVC User's Guide [UG89].

1.1 USE OF THIS VALIDATION SUMMARY REPORT

Consistent with the national laws of the originating country, the Ada Certification Body may make full and free public disclosure of this report. In the United States, this is provided in accordance with the "Freedom of Information Act" (5 U.S.C. #552). The results of this validation apply only to the computers, operating systems, and compiler versions identified in this report.

The organizations represented on the signature page of this report do not represent or warrant that all statements set forth in this report are accurate and complete, or that the subject implementation has no nonconformities to the Ada Standard other than those presented. Copies of this report are available to the public from the AVF which performed this validation or from:

National Technical Information Service
5285 Port Royal Road
Springfield, Virginia 22161
U.S.A.

Questions regarding this report or the validation test results should be directed to the AVF which performed this validation or to:

Ada Validation Organization
Computer and Software Engineering Division
Institute for Defense Analyses
1801 North Beauregard Street
Alexandria, Virginia 22311-1772
U.S.A.

1.3 ACVC TEST CLASSES

Compliance of Ada implementations is tested by means of the ACVC. The ACVC contains a collection of test programs structured into six test classes: A, B, C, D, E, and L. The first letter of a test name identifies the class to which it belongs. Class A, C, D, and E tests are executable. Class B and class L tests are expected to produce errors at compile time and link time, respectively.

The executable tests are written in a self-checking manner and produce a PASSED, FAILED, or NOT APPLICABLE message indicating the result when they are executed. Three Ada library units, the packages REPORT and SPPRT13, and the procedure CHECK_FILE are used for this purpose. The package REPORT also provides a set of identity functions used to defeat some compiler optimizations allowed by the Ada Standard that would circumvent a test objective. The package SPPRT13 is used by many tests for Chapter 13 of the Ada Standard. The procedure CHECK_FILE is used to check the contents of text files written by some of the Class C tests for Chapter 14 of the Ada Standard. The operation of REPORT and CHECK_FILE is checked by a set of executable tests. If these units are not operating correctly, validation testing is discontinued.

Class B tests check that a compiler detects illegal language usage. Class B tests are not executable. Each test in this class is compiled and the resulting compilation listing is examined to verify that all violations of the Ada Standard are detected. Some of the class B tests contain legal Ada code which must not be flagged illegal by the compiler. This behavior is also verified.

Class L tests check that an Ada implementation correctly detects violation of the Ada Standard involving multiple, separately compiled units. Errors are expected at link time, and execution is attempted.

In some tests of the ACVC, certain macro strings have to be replaced by implementation-specific values--for example, the

largest integer. A list of the values used for this implementation is provided in Appendix A. In addition to these anticipated test modifications, additional changes may be required to remove unforeseen conflicts between the tests and implementation-dependent characteristics. The modifications required for this implementation are described in section 2.3.

For each Ada implementation, a customized test suite is produced by the AVF. This customization consists of making the modifications described in the preceding paragraph, removing withdrawn tests (see section 2.1) and, possibly some inapplicable tests (see Section 3.2 and [UG89]).

In order to pass an ACVC an Ada implementation must process each test of the customized test suite according to the Ada Standard.

1.4 DEFINITION OF TERMS

Ada Compiler	The software and any needed hardware that have to be added to a given host and target computer system to allow transformation of Ada programs into executable form and execution thereof.
Ada Compiler Validation Capability (ACVC)	The means for testing compliance of Ada implementations, Validation consisting of the test suite, the support programs, the ACVC Capability User's Guide and the template for the validation summary (ACVC) report.
Ada Implementation	An Ada compiler with its host computer system and its target computer system.
Ada Joint Program Office (AJPO)	The part of the certification body which provides policy and guidance for the Ada certification Office system.
Ada Validation Facility (AVF)	The part of the certification body which carries out the procedures required to establish the compliance of an Ada implementation.
Ada Validation Organization (AVO)	The part of the certification body that provides technical guidance for operations of the Ada certification system.
Compliance of an Ada Implementation	The ability of the implementation to pass an ACVC version.

Computer System	A functional unit, consisting of one or more computers and associated software, that uses common storage for all or part of a program and also for all or part of the data necessary for the execution of the program; executes user-written or user-designated programs; performs user-designated data manipulation, including arithmetic operations and logic operations; and that can execute programs that modify themselves during execution. A computer system may be a stand-alone unit or may consist of several inter-connected units.
Conformity	Fulfillment by a product, process, or service of all requirements specified.
Customer	An individual or corporate entity who enters into an agreement with an AVF which specifies the terms and conditions for AVF services (of any kind) to be performed.
Declaration of Conformance	A formal statement from a customer assuring that conformity is realized or attainable on the Ada implementation for which validation status is realized.
Host Computer System	A computer system where Ada source programs are transformed into executable form.
Inapplicable Test	A test that contains one or more test objectives found to be irrelevant for the given Ada implementation.
ISO	International Organization for Standardization.
LRM	The Ada standard, or Language Reference Manual, published as ANSI/MIL-STD-1815A -1983 and ISO 8652-1987. Citations from the LRM take the form "<section>.<subsection>:<paragraph>."
Operating System	Software that controls the execution of programs and that provides services such as resource allocation, scheduling, input/output control, and data management. Usually, operating systems are predominantly software, but partial or complete hardware implementations are possible.
Target Computer System	A computer system where the executable form of Ada programs are executed.

Validated Ada Compiler	The compiler of a validated Ada implementation.
Validated Ada Implementation	An Ada implementation that has been validated successfully either by AVF testing or by registration [Pro92].
Validation	The process of checking the conformity of an Ada compiler to the Ada programming language and of issuing a certificate for this implementation.
Withdrawn Test	A test found to be incorrect and not used in conformity testing. A test may be incorrect because it has an invalid test objective, fails to meet its test objective, or contains erroneous or illegal use of the Ada programming language.

CHAPTER 2

IMPLEMENTATION DEPENDENCIES

2.1 WITHDRAWN TESTS

Some tests are withdrawn by the AVO from the ACVC because they do not conform to the Ada Standard. The following 104 tests had been withdrawn by the Ada Validation Organization (AVO) at the time of validation testing. The rationale for withdrawing each test is available from either the AVO or the AVF. The publication date for this list of withdrawn tests is 93-11-22.

CE3814A	CE3902B				

2.2 INAPPLICABLE TESTS

A test is inapplicable if it contains test objectives which are irrelevant for a given Ada implementation. The inapplicability criteria for some tests are explained in documents issued by ISO and the AJPO known as Ada Commentaries and commonly referenced in the format AI-ddddd. For this implementation, the following tests were determined to be inapplicable for the reasons indicated; references to Ada Commentaries are included as appropriate.

The following 201 tests have floating-point type declarations requiring more digits than SYSTEM.MAX_DIGITS:

C24113L..Y (14 tests)	C35705L..Y (14 tests)
C35706L..Y (14 tests)	C35707L..Y (14 tests)

C35708L..Y (14 tests)	C35802L..Z (15 tests)
C45241L..Y (14 tests)	C45321L..Y (14 tests)
C45421L..Y (14 tests)	C45521L..Z (15 tests)
C45524L..Z (15 tests)	C45621L..Z (15 tests)
C45641L..Y (14 tests)	C46012L..Z (15 tests)

C35713B, C45423B, B86001T, and C86006H check for the predefined type `SHORT_FLOAT`; for this implementation, there is no such type.

C35713D and B86001Z check for a predefined floating-point type with a name other than `FLOAT`, `LONG_FLOAT`, or `SHORT_FLOAT`; for this implementation, there is no such type.

C45423A, C45523A, and C45622A check that the proper exception is raised if `MACHINE_OVERFLOW` is `TRUE` and the results of various floating-point operations lie outside the range of the base type; for this implementation, `MACHINE_OVERFLOW` is `FALSE`.

C45531M..P and C45532M..P (8 tests) check fixed-point operations for types that require a `SYSTEM.MAX_MANTISSA` of 47 or greater; for this implementation, `MAX_MANTISSA` is less than 47.

B86001Y uses the name of a predefined fixed-point type other than type `DURATION`; for this implementation, there is no such type.

CA2009F checks whether a generic non-library subprogram can be instantiated before the separate compilation of its body (and any of its subunits); this implementation requires that the body and subunits of a generic non-library subprogram be in the same compilation as the specification if instantiations precede them. (See section 2.3.) }

LA3004B, EA3004D, and CA3004F check `pragma INLINE` for functions; this implementation does not support `pragma INLINE` for functions.

CD1009C checks whether a length clause can specify a non-default size for a floating-point type; this implementation does not support such sizes.

CD2A84A, CD2A84E, CD2A84I..J (2 tests), and CD2A84O use length clauses to specify non-default sizes for access types; this implementation does not support such sizes.

AE2101C and EE2201D..E (2 tests) use instantiations of package `SEQUENTIAL_IO` with unconstrained array types and record types with discriminants without defaults; these instantiations are rejected by this compiler.

AE2101H, EE2401D, and EE2401G use instantiations of package `DIRECT_IO` with unconstrained array types and record types with discriminants without defaults; these instantiations are rejected

by this compiler.

The 21 tests listed in the following table check that USE_ERROR is raised if the given file operations are not supported for the given combination of mode and access method; this implementation supports these operations.

Test	File Operation	Mode	File Access Method
CE2102D	CREATE	IN_FILE	SEQUENTIAL_IO
CE2102E	CREATE	OUT_FILE	SEQUENTIAL_IO
CE2102F	CREATE	INOUT_FILE	DIRECT_IO
CE2102I	CREATE	IN_FILE	DIRECT_IO
CE2102J	CREATE	OUT_FILE	DIRECT_IO
CE2102N	OPEN	IN_FILE	SEQUENTIAL_IO
CE2102O	RESET	IN_FILE	SEQUENTIAL_IO
CE2102P	OPEN	OUT_FILE	SEQUENTIAL_IO
CE2102Q	RESET	OUT_FILE	SEQUENTIAL_IO
CE2102R	OPEN	INOUT_FILE	DIRECT_IO
CE2102S	RESET	INOUT_FILE	DIRECT_IO
CE2102T	OPEN	IN_FILE	DIRECT_IO
CE2102U	RESET	IN_FILE	DIRECT_IO
CE2102V	OPEN	OUT_FILE	DIRECT_IO
CE2102W	RESET	OUT_FILE	DIRECT_IO
CE3102E	CREATE	IN_FILE	TEXT_IO
CE3102F	RESET	Any Mode	TEXT_IO
CE3102G	DELETE	-----	TEXT_IO
CE3102I	CREATE	OUT_FILE	TEXT_IO
CE3102J	OPEN	IN_FILE	TEXT_IO
CE3102K	OPEN	OUT_FILE	TEXT_IO

The following 16 tests check operations on sequential, direct, and text files when multiple internal files are associated with the same external file and one or more are open for writing; USE_ERROR is raised when this association is attempted.

CE2107B..E	CE2107G..H	CE2107L	CD2110B	CE2110D
CE2111D	CE2111H	CE3111B	CE3111D..E	CE3114B
CE3115A				

CE2203A checks that WRITE raises USE_ERROR if the capacity of an external sequential file is exceeded; this implementation cannot restrict file capacity.

CE2403A checks that WRITE raises USE_ERROR if the capacity of an external direct file is exceeded; this implementation cannot restrict file capacity.

CE3304A checks that SET_LINE_LENGTH and SET_PAGE_LENGTH raise USE_ERROR if they specify an inappropriate value for the external file; there are no inappropriate values for this implementation.

CE3413B checks that PAGE raises LAYOUT ERROR when the value of the page number exceeds COUNT'LAST; for this implementation, the value of COUNT'LAST is greater than 150000, making the checking of this objective impractical.

2.3 TEST MODIFICATIONS

Modifications (see section 1.3) were required for 6 tests.

The following tests were split into two or more tests because this implementation did not report the violations of the Ada Standard in the way expected by the original tests.

B22003A B83033B B85013D

CA2009F was graded inapplicable by Evaluation Modification as directed by the AVO. This test contains instantiations of a generic non-library subprograms prior to the compilation of their bodies; as allowed by AI-00408 and AI-00506, the compilation of the generic subprogram bodies (subunits) makes the compilation unit that contains the instantiations obsolete.

BC3204C and BC3205D were graded passed by Processing Modification as directed by the AVO. These tests check that instantiations of generic units with unconstrained types as generic actual parameters are illegal if the generic bodies contain uses of the types that require a constraint. However, the generic bodies are compiled after the units that contain the instantiations, and this implementation creates a dependence of the instantiating units on the generic units as allowed by AI-00408 and AI-00506 such that the compilation of the generic bodies makes the instantiating units obsolete--no errors are detected. The processing of these tests was modified by re-compiling the obsolete units; all intended errors were then detected by the compiler.

CHAPTER 3

PROCESSING INFORMATION

3.1 TESTING ENVIRONMENT

The Ada implementation tested in this validation effort is described adequately by the information given in the initial pages of this report.

For technical and sales information about this Ada implementation, contact:

Mr. David Hicks
TISOFT, INC.
10521 Rosehaven Street
Suite 200
Fairfax, VA 22030 (U.S.A.)

Testing of this Ada implementation was conducted at the customer's site by a validation team from the AVF.

3.2 SUMMARY OF TEST RESULTS

An Ada Implementation passes a given ACVC version if it processes each test of the customized test suite in accordance with the Ada Programming Language Standard, whether the test is applicable or inapplicable; otherwise, the Ada Implementation fails the ACVC [Pro92].

For all processed tests (inapplicable and applicable), a result was obtained that conforms to the Ada Programming Language Standard.

The list of items below gives the number of ACVC tests in various categories. All tests were processed, except those that were withdrawn because of test errors (item b; see section 2.1). All tests passed, except those that are listed in sections 2.1 and 2.2 (counted in items b and f, below).

a) Total Number of Applicable Tests	3790
b) Total Number of Withdrawn Tests	104
c) Processed Inapplicable Tests	276
d) Non-Processed I/O Tests	0
e) Non-Processed Floating-Point Precision Tests	0

f) Total Number of Inapplicable Tests	276	(c+d+e)
g) Total Number of Tests for ACVC 1.11	4170	(a+b+f)

3.3 TEST EXECUTION

A magnetic tape containing the customized test suite (see section 1.3) was taken on-site by the validation team for processing. The contents of the magnetic tape were loaded directly onto the host/target computer.

After the test files were loaded onto the host computer, the full set of tests was processed by the Ada implementation.

The tests were compiled, linked, and executed on the host/target computer system. The results were captured on the host/target computer system.

Testing was performed using command scripts provided by the customer and reviewed by the validation team. See Appendix B for a complete listing of the processing options for this implementation. The options invoked explicitly for validation testing during this test were:

-fwE

Test output, compiler and linker listings, and job logs were captured on magnetic tape and archived at the AVF. The listings examined on-site by the validation team were also archived.

APPENDIX A

MACRO PARAMETERS

This appendix contains the macro parameters used for customizing the ACVC. The meaning and purpose of these parameters are explained in [UG89]. The parameter values are presented in two tables. The first table lists the values that are defined in terms of the maximum input-line length, which is the value for \$MAX_IN_LEN--also listed here. These values are expressed here as Ada string aggregates, where "V" represents the maximum input-line length.

Macro Parameter	Macro Value
\$MAX_IN_LEN	200 -- Value of V
\$BIG_ID1	(1..V-1 => 'A', V => '1')
\$BIG_ID2	(1..V-1 => 'A', V => '2')
\$BIG_ID3	(1..V/2 => 'A') & '3' & (1..V-1-V/2 => 'A')
\$BIG_ID4	(1..V/2 => 'A') & '4' & (1..V-1-V/2 => 'A')
\$BIG_INT_LIT	(1..V-3 => '0') & "298"
\$BIG_REAL_LIT	(1..V-5 => '0') & "690.0"
\$BIG_STRING1	'"' & (1..V/2 => 'A') & '"'
\$BIG_STRING2	'"' & (1..V-1-V/2 => 'A') & '1' & '"'
\$BLANKS	(1..V-20 => ' ')
\$MAX_LEN_INT_BASED_LITERAL	"2:" & (1..V-5 => '0') & "11:"
\$MAX_LEN_REAL_BASED_LITERAL	"16:" & (1..V-7 => '0') & "F.E:"
\$MAX_STRING_LITERAL	'"' & (1..V-2 => 'A') & '"'

The following table contains the values for the remaining macro parameters.

Macro Parameter	Macro Value
\$ACC_SIZE	32
\$ALIGNMENT	4
\$COUNT_LAST	2_147_483_646
\$DEFAULT_MEM_SIZE	1024
\$DEFAULT_STOR_UNIT	8
\$DEFAULT_SYS_NAME	PENTIUM
\$DELTA_DOC	2.0**(-31)
\$ENTRY_ADDRESS	16#0#
\$ENTRY_ADDRESS1	16#1#
\$ENTRY_ADDRESS2	16#2#
\$FIELD_LAST	2_147_483_647
\$FILE_TERMINATOR	' '
\$FIXED_NAME	NO_SUCH_FIXED_TYPE
\$FLOAT_NAME	NO_SUCH_FLOAT_TYPE
\$FORM_STRING	""
\$FORM_STRING2	"CANNOT RESTRICT FILE CAPACITY"
\$GREATER_THAN_DURATION	90_000.0
\$GREATER_THAN_DURATION_BASE_LAST	10_000_000.0
\$GREATER_THAN_FLOAT_BASE_LAST	3.5E+38
\$GREATER_THAN_FLOAT_SAFE_LARGE	3.4E+38
\$GREATER_THAN_SHORT_FLOAT_SAFE_LARGE	

	1.0E+308
\$HIGH_PRIORITY	20
\$ILLEGAL_EXTERNAL_FILE_NAME1	/NODIRECTORY/FILENAME1

APPENDIX B

COMPILATION SYSTEM OPTIONS

The compiler options of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this appendix are to compiler documentation and not to this report.

12.1 ada

12.1.1 Invocation

`ada [option...] file .ada ...`

12.1.2 Description

The **ada** command invokes the Green Hills Ada compiler. A program library must be created using **mklib** or **newlib** in advance of any compilation. The compiler aborts if it is unable to find a program library (either the default, **ada.lib**, in the current working directory or the library name specified with the **-L** option).

Note that the source file has the extension **.ada**. Just about any non-empty file extension is permitted. The ones not allowed include those used by the Green Hills Ada compiling system for other purposes such as **.o** for object module files. If an illegal extension is given, the error message "**missing or improper file name**" is displayed. Some other commonly used source file extensions are:

- .ads** for package specification source files
- .adb** for package body source files
- .sub** for subunit (separate) source files

12.1.3 Options

Following are the target independent options to the **ada** command:

- D** Use IEEE double precision for Ada type float.
- fC** Compile the source file only if necessary, either because the source file has been updated or because a dependent unit has been recompiled.
- fE** Generate error log file. The **-fE** option causes the compiler to generate a log file containing all the error messages and warning messages produced during compilation. The error log file has the same name as the source file, with the extension **.err**. For example, the error log file for **simple.ada** is **simple.err**. The error log file is placed in the current working directory. In the absence of the **-fE** option, the error log information is sent to the standard output stream.
- fL** Generate exception location information. The **-fL** option causes location information (source file names and line numbers) to be maintained for internal checks. This information is useful for debugging in the event that an "Exception never handled" message appears when an exception propagates out of the main program. This option causes the code to be somewhat larger. If **-fL** is not used, exceptions that propagate out of the main program will behave in the same way, but no location information will be printed with the "Exception never handled" message.
- fN** Suppress numeric checking. The **-fN** option suppresses two kinds of numeric checks for the entire compilation:

1. **division_check**
2. **overflow_check**

These checks are described in section 11.7 of the LRM. Using **-fN** reduces the size of the code. Note that there is a related **ada** option, **-fs** to suppress all checks for a compilation. See also section 2.4.2.

The **-fN** option must be used in place of pragma **suppress** for the two numeric checks, because presently pragma **suppress** is not supported for **division_check** and **overflow_check**.

Pragma **suppress** works for other checks, as described in section 2.4.2. In the absence of the **-fN** option, the numeric checks are always performed.

- fo** When used with the **-fC** option, prevents harmless changes to low level units from forcing recompilation of the source file.
- fs** Suppress all checks. The **-fs** option suppresses all automatic checking, including numeric checking. This option is equivalent to using pragma **suppress** on all checks. This option reduces the size of the code, and is good for producing "production quality" code or for benchmarking the compiler. Note that there is a related **ada** option, **-fN** to suppress only certain kinds of numeric checks. See also section 2.4.2.
- fU** Inhibit library update. The **-fU** option inhibits library updates. This is of use in conjunction with the **-S** option. Certain restrictions apply to the use of this option; see section 12.1.9.
- fv** Compile verbosely. The compiler prints the name of each subprogram, package, or generic as it is compiled.
- fw** Suppress warning messages. With this option, the compiler does not print warning messages about ignored pragmas, exceptions that are certain to be raised at run-time, or other potential problems that the compiler is otherwise forbidden to deem as errors by the LRM.
- G** Generate debug information for Green Hills Software 'Multi' debugger.
- help** Display simple help on the compiler and compiler driver options.

-lmodifiers

Generate listing file. The **-l** option causes the compiler to create a listing. Optional modifiers can be given to affect the listing format. You can use none or any combination of the following modifiers:

- c** continuous listing format
- p** obey pragma **page** directives
- s** use standard output
- t** relevant text output only

The formats of and options for listings are discussed in section 12.1.7. The default listing file generated has the same name as the source file, with the extension **.lst**. For example, the default listing file produced for **simple.ada** has the name **simple.lst**. The listing file is placed in the current working directory. Note: **-l** also causes an error log file to be produced, as with the **-fE** option.

-Llibrary-name

Default: **ada.lib**

Use alternate library. The **-L** option specifies an alternative name for the program library.

- N** No compile. This option causes the **ada** command to do a "dry run" of the compilation process. The command invoked for each processing step is printed. This is similar to the **-P** option, but no actual processing is performed.

-OLAIMS

Perform optimizations (see Chapter 5).

- P** Print compile. This option causes the **ada** command to print out the command invoked for each processing step as it is performed.
- p** Generate code to be profiled.
- S** Produce assembly code. Causes the code generator to produce an assembly language source file and to halt further processing. This option must be used cautiously; refer to section 12.1.9 for more information.

-Xnnn Turn on the **-Xnnn** option where *nnn* is a three digit integer.

-Znnn Turn off the **-Xnnn** option where *nnn* is a three digit integer.

Note: Options beginning with **-f** can be combined, as in "**-fsv**." This is equivalent to specifying the options separately, e.g. "**-fs -fv**." Options beginning with **-l** can be similarly combined or separated, as in "**-lcs**" or "**-lc -ls**" (see section 12.1.7).

12.1.4 Compiler Output Files

Files produced by compilations, other than listings and error logs, are:

- .s** files assembly language files (only when **-S** option used)
- .atr** files interface description files
- .gnn** files generic description files; *nn* is a two-digit number
- .o** files object code files
- .sep** files subunit environment description files

Also produced are various intermediate files; these are usually deleted as a matter of course. You normally need not concern yourself with most of these output files with the exception of assembly language files.

Output files are placed either in the current working directory or in the auxiliary directory, depending on the configuration of the program library (as determined by **mklib** or **newlib**). The name of an auxiliary directory associated with a program library can be determined by using the **-h** option to the **lslib** command.

The name of an output file is derived from the compilation unit name, but when a name collision occurs, the library system assigns an arbitrary unique name that may bear no relation to the source file name (it might look like "aaaaaab"). The **-l** option to the **lslib** command must be used to determine the base name used to derive the output file names for a particular library entry. The base name is displayed as the "Host system file name".

The name of an output file is derived from the compilation unit name.

Supplementary files that may be produced by a compilation are:

- .err** files error log files (only when **-fE** option used)
- .lst** files listing files (only when **-l** option used)

These are discussed in section 12.1.7.

12.1.5 Non-Local Compilations

The compiler is able to compile files that reside in directories other than the current working directory. As always, a program library (typically **ada.lib**) must be present in the current working directory. All output files are placed in the current working directory or in the local auxiliary directory (**ada.aux**).

12.1.6 Compile-Time Error Messages

When syntactic or semantic errors are detected in the source code, the Meridian AdaAdaStudent compiler produces either error messages or warning messages. These messages are normally produced on the standard output stream. If the **-fE** option is given, these messages are written, instead, to an error log file. The error log file has the same name as the source file, with the extension **.err**.

When error messages are printed, processing does not proceed beyond the first pass. No object code file is produced. Warning messages do not prevent further processing. Other passes (e.g. the code generator) may print error messages as well, but these are almost certain to be error messages related to problems internal to the compiler itself, and should be reported to Green Hills Software.

Error messages have the form:

"*filename*", *nn*: English explanation of error [**LRM** *l.m.n/p*]

LINKER OPTIONS

The linker options of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this appendix are to linker documentation and not to this report.

12.7 bamp

12.7.1 Invocation

bamp [*option* ...] [*main-procedure-name*]

12.7.2 Description

The **bamp** (Build Ada Main Program) command creates an executable program given the name of the main subprogram. The *main-procedure-name* given to **bamp** must be a parameterless procedure that has already been compiled.

Note: Be careful not to confuse the name of the source file containing the main subprogram (e.g. *simple.ada*) with the actual name of the main subprogram (e.g. *simple*).

If a *main-procedure-name* is not specified on the **bamp** command line, **bamp** links using the last-compiled subprogram that fits the profile for a main subprogram. To determine which subprogram will be used when no main subprogram is given to **bamp**, use the **lslib -t** option. When in doubt, it may be best to specify the main subprogram explicitly.

For example, you can compile and link programs as in this example:

```
ada simple.ada
bamp
```

When **bamp** runs, it prints out "bamp simple" to indicate that it is linking *simple*, the most recently compiled main subprogram.

Note that when no main subprogram is specified, **bamp** selects the most recently compiled subprogram, not the most recently linked subprogram. If several different main subprograms are linked between compiles, still the most recently compiled subprogram is selected if no subprogram is explicitly specified.

The **bamp** program functions as a high-level linker. It works by creating a top-level main program that contains all necessary context clauses and calls to package elaboration procedures. The main program is created as an internal form file on which the code generator is run. Following this code generation pass, all the required object files are linked.

12.7.3 Options

-f Suppress main program generation step. The **-f** option suppresses the creation and additional code generation steps for the temporary main program file. The **-f** option can be used when a simple change has been made to the body of a compilation unit. If unit elaboration order is changed, or if the specification of a unit is changed, or if new units are added, then this option should not be used. The **-f** option saves a few seconds, but places an additional bookkeeping burden on you. The option should be avoided under most circumstances. Note that invoking **bamp** with the **-n** option followed by another invocation of **bamp** with the **-f** option has the same effect as an invocation of **bamp** with neither option (**-n** and **-f** neutralize each other).

-L *library-name*

Default: **ada.lib**

Use alternate library. The **-L** option specifies the name of the program library to be consulted by the **bamp** program. This option overrides the default library name.

-m Produce a primitive load map. The **-m** option causes a listing of the names of the files which will be loaded to be emitted.

-n No link. The **-n** option suppresses actual object file linkage, but creates and performs code generation on the main program file. Note that invoking **bamp** with the **-n** option followed by another

invocation of **bamp** with the **-f** option has the same effect as an invocation of **bamp** with neither option. That is, **-n** and **-f** neutralize each other.

-N No operations. The **-N** option causes the **bamp** command to do a "dry run"; it prints out the actions it takes to generate the executable program, but does not actually perform those actions. The same kind of information is printed by the **-P** option.

-o output-file-name

Use alternate executable file output name. The **-o** option specifies the name of the executable program file written by the **bamp** command. This option overrides the default output file name.

-p The **-p** option enables profiling of the created executable. This option should also have been sent to the **ada** command when the source was compiled.

-P Print operations. The **-P** option causes the **bamp** command to print out the actions it takes to generate the executable program as the actions are performed.

-Q relocatable-link-file

Link in an extra file. The **-Q** option instructs the **bamp** command to link in another object file. This is useful for inter-language programming. By using the **pragma interface** facility and the **-Q** option to **bamp**, writing Ada code that calls routines written in other languages is possible.

-r Create re-linkable output. The **-r** option causes an object file to be generated rather than an executable file. The resulting file contains all symbol and relocation information, and can then be used with any low-level linker.

-v Link verbosely. The **-v** option causes the **bamp** command to print out information about what actions it takes in building the main program such as:

- The name of the program library consulted.
- The library search order (listed as "uses" of the library units used by the program).
- The name of the main program file created (as opposed to the main procedure name).
- The elaboration order.
- The total program stack size.
- The name of the executable load module created.
- The verbose code generation for the main program file.

-W Suppress warnings. This option allows you to suppress warnings from the optimizer.

12.7.4 Examples

Example 1

Link main subprogram **simple** in the usual manner:

```
bamp simple
```

This creates an executable named **simple**.

Example 2

Link the most recently compiled main subprogram:

```
bamp
```

When no subprogram is specified, the **bamp** program displays the name of the library unit being linked as the main subprogram. Note that **bamp** selects the most recently compiled subprogram, not the most recently linked subprogram.

APPENDIX C

APPENDIX F OF THE Ada STANDARD

The only allowed implementation dependencies correspond to implementation-dependent pragmas, to certain machine-dependent conventions as mentioned in Chapter 13 of the Ada Standard, and to certain allowed restrictions on representation clauses. The implementation-dependent characteristics of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this Appendix are to compiler documentation and not to this report. Implementation-specific portions of the package STANDARD, which are not a part of Appendix F, are:

package STANDARD is

```
type BYTE_INTEGER is range -128 .. 127;
type SHORT_INTEGER is range -32768 .. 32767;
type INTEGER is range -2147483648 .. 2147483647;
type LONG_INTEGER is range -2147483648 .. 2147483647;

type FLOAT is digits 6 range -3.40282346638529E+38 ..
                        3.40282346638529E+38;
type LONG_FLOAT is digits 15 range
                        -1.79769313486213e+308 ..
                        1.79769313486213e+308;

type DURATION is delta 0.0001 range -86400.0 .. 86400.0;

end STANDARD;
```

Appendix F Implementation-Dependent Characteristics

This appendix lists implementation-dependent characteristics of Green Hills Ada. Note that there are no preceding appendices. This appendix is called *Appendix F* in order to comply with the Reference Manual for the Ada Programming Language* (LRM) ANSI/MIL-STD-1815A which states that this appendix be named Appendix F.

Implemented Chapter 13 features include length clauses, enumeration representation clauses, record representation clauses, address clauses, interrupts, package **system**, machine code insertions, pragma **interface**, and unchecked programming.

F.1 Pragmas

The implemented pre-defined pragmas are:

elaborate	See the LRM section 10.5.
interface	See section F.1.1.
list	See the LRM Appendix B.
pack	See section F.1.2.
page	See the LRM Appendix B.
priority	See the LRM Appendix B.
suppress	See section F.1.3.
inline	See the LRM section 6.3.2

The remaining pre-defined pragmas are accepted, but presently ignored:

controlled
optimize
system_name
shared
storage_unit
memory_size

Named parameter notation for pragmas is not supported.

When illegal parameter forms are encountered at compile time, the compiler issues a warning message rather than an error, as required by the Ada language definition. Refer to the LRM Appendix B for additional information about the pre-defined pragmas.

F.1.1 Pragma Interface

The form of pragma **interface** in Green Hills Ada is:

```
pragma interface( language, subprogram [, "link-name" ] );
```

where:

<i>language</i>	This is the interface language, one of the names assembly , builtin , c or internal . The names builtin and internal are reserved for use by Green Hills compiler maintainers in run-time support packages.
<i>subprogram</i>	This is the name of a subprogram to which the pragma interface applies. If <i>link-name</i> is omitted, then the Ada <i>subprogram</i> name is also used as the object code symbol name. Depending on the language specified, some automatic modifications may be made to the object code symbol name.
<i>link-name</i>	This is an optional string literal specifying the name of the non-Ada subprogram corresponding to the Ada subprogram named in the second parameter. If <i>link-name</i> is omitted, then <i>link-name</i> defaults to the value of <i>subprogram</i> translated to lowercase. Depending on the language specified, some automatic modifications may be made to the <i>link-name</i> to produce the actual object code symbol name that is generated whenever references are made to the corresponding Ada subprogram. It is appropriate to use the optional <i>link-name</i> parameter to pragma interface only when the interface subprogram has a name that does not correspond at all to its Ada identifier or when the interface subprogram name cannot be given using rules for constructing Ada identifiers (e.g. if the name contains a '\$' character).

The characteristics of object code symbols generated for each interface language are:

assembly	The object code symbol is the same as <i>link-name</i> . If no <i>link-name</i> string is specified, then the subprogram name is translated to lowercase.
builtin	The object code symbol is the same as <i>link-name</i> , but prefixed with the string, "_mss_". This language interface is reserved for special interfaces defined by Green Hills Software, Inc. The builtin interface is presently used to declare certain low-level run-time operations whose names must not conflict with programmer-defined or language system defined names.
c	The object code symbol is the same as <i>link-name</i> , but with one underscore character ('_') prepended. This is the convention used by the C compiler. If no <i>link-name</i> string is specified, then the subprogram name is translated to lowercase.
internal	No object code symbol is generated for an internal language interface; this language interface is reserved for special interfaces defined by Green Hills Software, Inc. The internal interface is presently used to declare certain machine-level bit operations.

No automatic data conversions are performed on parameters of any interface subprograms. It is up to the programmer to ensure that calling conventions match and that any necessary data conversions take place when calling interface subprograms.

A pragma **interface** may appear within the same declarative part as the subprogram to which the pragma **interface** applies, following the subprogram declaration, and prior to the first use of the subprogram. A pragma **interface** that applies to a subprogram declared in a package specification must occur within the same package specification as the subprogram declaration; the pragma **interface** may not appear in the package body in this case. A pragma **interface** declaration for either a private or nonprivate subprogram declaration may appear in the private part of a package specification.

Pragma **interface** for library units is not supported.

Refer to the LRM section 13.9 for additional information about pragma **interface**.

F.1.2 Pragma Pack

Pragma **pack** is implemented for composite types (records and arrays).

Pragma pack is permitted following the composite type declaration to which it applies, provided that the pragma occurs within the same declarative part as the composite type declaration, before any objects or components of the composite type are declared.

Note that the declarative part restriction means that the type declaration and accompanying **pragma pack** cannot be split across a package specification and body.

The effect of **pragma pack** is to minimize storage consumption by discrete component types whose ranges permit packing. Use of **pragma pack** does not defeat allocations of alignment storage gaps for some record types. **Pragma pack** does not affect the representations of real types, pre-defined integer types, and access types.

F.1.3 Pragma Suppress

Pragma suppress is implemented as described in the LRM section 11.7, with these differences:

- Presently, **division_check** and **overflow_check** must be suppressed via a compiler flag, **-fN**; **pragma suppress** is ignored for these two numeric checks.
- The optional "ON =>" parameter name notation for **pragma suppress** is ignored.
- The optional second parameter to **pragma suppress** is ignored; the pragma always applies to the entire scope in which it appears.

F.2 Attributes

All attributes described in the LRM Appendix A are supported.

F.3 Standard Types

Additional standard types are defined in Green Hills Ada:

- **byte_integer**
- **short_integer**
- **long_integer**

The standard numeric types are defined as:

```

type byte_integer is range -128 .. 127;
type short_integer is range -32768 .. 32767;
type integer is range -2147483648 .. 2147483647;
type long_integer is range -2147483648 .. 2147483647;
type float is digits 6
  range -3.40282E+38 .. 3.40282E+38;
type long_float is digits 15
  range -1.79769313486231E+308 .. 1.79769313486231E+308;
type duration is delta 0.0001 range -86400.0000 .. 86400.0000;
```

F.4 Package System

The specification of package **system** is:

```

package system is
  type address is new long_integer;
  type name is (pentium);
  system_name : constant name := pentium;
  type target_systems is (
```

```

        unix,
        netos,
        vms,
        msdos,
        bare,
        mac );
type target_machines is (
    vax,
    z8001,
    z8002,
    z80000,
    m68000,
    m68020,
    m68030,
    m88000,
    i8086,
    i80286,
    i80386,
    i80486,
    i860,
    R2000,
    R3000,
    RS6000,
    HPFA,
    sparc,
    pentium );
target_system : constant target_systems := unix;
target_system : constant target_machines := pentium;
storage_unit  : constant := 8;
memory_size   : constant := 1024;
-- System-Dependent Named Numbers
min_int       : constant := -2147483648;
max_int       : constant := 2147483647;
max_digits    : constant := 15;
max_mantissa  : constant := 31;
fine_delta    : constant := 2.0 ** (-31);
tick          : constant := 0.01001;
-- Other System-Dependent Declarations
subtype priority is integer range 1 .. 20;

```

The value of `system.memory_size` is presently meaningless.

F.5 Restrictions on Representation Clauses

Green Hills Ada supports representation clauses including length clauses, enumeration representation clauses, record representation clauses and address clauses.

F.5.1 Length Clauses

A size specification (**t'size**) is rejected if fewer bits are specified than can accommodate the type. The minimum size of a composite type may be subject to application of pragma **pack**. It is permitted to specify precise sizes for unsigned integer ranges, e.g. 8 for the range **0..255**. However, because of requirements imposed by the Ada language definition, a full 32-bit range of unsigned values, i.e. **0..(2**32)-1**, cannot be defined, even using a size specification.

The specification of collection size (**t'storage_size**) is evaluated at run-time when the scope of the type to which the length clause applies is entered, and is therefore subject to rejection (via **storage_error**) based on available storage at the time the allocation is made. A collection may include storage used for run-time administration of the collection, and therefore should not be expected to accommodate a specific number of objects. Furthermore, certain classes of objects such as unconstrained discriminant array components of records may be allocated outside a given collection, so a collection may accommodate more objects than might be expected.

The specification of storage for a task activation (**t'storage_size**) is evaluated at run-time when a task to which the length clause applies is activated, and is therefore subject to rejection (via **storage_error**) based on available storage at the time the allocation is made. Storage reserved for a task activation is separate from storage needed for any collections defined within a task body.

The specification of small for a fixed point type (**t'small**) is subject only to restrictions defined in the LRM section 13.2.

F.5.2 Enumeration Representation Clauses

The internal code for the literal of an enumeration type named in an enumeration representation clause must be in the range of **standard.integer**.

The value of an internal code may be obtained by applying an appropriate instantiation of **unchecked_conversion** to an integer type.

F.5.3 Record Representation Clauses

The storage unit offset (the **at static_simple_expression** part) is given in terms of 8-bit storage units and must be even.

A bit position (the **range** part) applied to a discrete type component may be in the range **0..15**, with 0 being the least significant bit of a component. A **range** specification may not specify a size smaller than can accommodate the component. A **range** specification for a component not accommodating bit packing may have a higher upper bound as appropriate (e.g. **0..31** for a discriminant **string** component). Refer to the internal data representation of a given component in determining the component size and assigning offsets.

Components of discrete types for which bit positions are specified may not straddle 16-bit word boundaries.

The value of an alignment clause (the optional **at mod** part) must evaluate to 1, 2, 4, or 8, and may not be smaller than the highest alignment required by any component of the record.

F.5.4 Address Clauses

An address clause may be supplied for an object (whether constant or variable) or a task entry, but not for a subprogram, package, or task unit. The meaning of an address clause supplied for a task entry is given in section F.5.5.

An address expression for an object is a 32-bit linear segmented memory address of type **system.address**.

F.5.5 Interrupts

A task entry's address clause can be used to associate the entry with a UNIX signal. Values in the range 0..31 are meaningful, and represent the signals corresponding to those values.

An interrupt entry may not have any parameters.

F.5.6 Change of Representation

There are no restrictions for changes of representation effected by means of type conversion.

F.6 Implementation-Dependent Components

No names are generated by the implementation to denote implementation-dependent components.

F.7 Machine Code Insertions

Machine code insertions are explained in section 8.2.

F.8 Unchecked Programming

The Green Hills Ada compiler supports the unchecked programming generic library subprograms **unchecked_deallocation** and **unchecked_conversion**. There are no restrictions on the use of **unchecked_conversion**. Conversions between objects whose sizes do not conform may result in storage areas with undefined values.

F.9 Input-Output Packages

A summary of the implementation-dependent input-output characteristics is:

- In calls to **open** and **create**, the *form* parameter must be the empty string (the default value).
- More than one internal file can be associated with a single external file for reading only. For writing, only one internal file may be associated with an external file; Do not use **reset** to get around this rule.
- Temporary sequential and direct files are given names. Temporary files are deleted when they are closed.
- File I/O is buffered; text files associated with terminal devices are line-buffered.
- The packages **sequential_io** and **direct_io** cannot be instantiated with unconstrained composite types or record types with discriminants without defaults.
